November 2016

In our network experiments of collective risk-taking, subjects repeatedly enacted a lottery which rewarded global risk-taking if the majority took action and penalized taking risk if the attempt at mobilization failed. A total of 720 subjects finished the full experimental session in 45 random network realizations, 15 realizations for each treatment; subjects were recruited from Amazon Mechanical Turk (AMT), an online labor market for Human Intelligence Tasks (HITs), a common source of subjects for such experiments.

The author thanks Human Nature Lab at Yale Institute for Network Science for providing funding, and Dominik Duell and Mark McKnight for research assistance.

Variable Name	Description of Variable
<code>subject_number</code>	assigned subject ID
<code>network_degree</code>	subject's network degree
<code>stage</code>	experiment stage
<code>treatment</code>	treatment (T1: central, T2: random, T3: peripheral)
<code>session</code>	session number (1–15 for each treatment)
<code>round</code>	round number(1–15 for each session)
<code>action</code>	action taken by subject
<code>subject_rank</code>	subject's risk rank
<code>centrality</code>	subject's betweenness centrality
<code>mean_action_neighbors</code>	average rate of action rate among subject's network neighbors in the previous round
<code>mean_rank_neighbors</code>	average risk rank of subject's network neighbors
